## Introduction to Computer Engineering

→ our own chapter, not Givone's chapter  
Dr. Minsu Choi

Ch1. Introduction to Concepts in Digital Systems & Computer Arithmetic

(= Givone ch1 & 2)

UNIVERSITY OF MISSOURI-ROLLA  
The Name. The Degree. The Difference.

## What is a Digital System?

- A digital system is an electronic network that processes information using only digits (numbers) to implement calculations and operations.
- Binary number system is used for digital systems in general.

## Binary number system

- The mostly used number system for a digital system.
- Base-2 number system (e.g., base-10 - decimal, base-8 - octal, base-16 - hexadecimal, etc)
- Each digit can be either a value of 0 or 1. The number themselves (0 or 1) are called bits (e.g., 0101 is 4-digit binary number)

## Digital system tasks

- Input translation: translates information from our world into a binary "language" that can be understood by the digital network.
- Data processing: performs the required calculations and operations using only the binary digits 0 and 1.
- Output: returns an answer to our world in a form that can we understand.

*we can*

## Views of a Digital System

- A digital network can be viewed in different ways:
  - Hierarchies - primitive units -> more complex units -> even larger units.
  - Logic networks - digital network is based on the behavior of Binary numbers. It is possible to describe any digital network in terms of the fact that groups of binary variable can be used to represent virtually any set of data.
  - Electrical circuits - the physical realization of a digital network is accomplished by using electronic components that control the flow of electric current in a manner that implements logic operations.
  - Formal description - it is possible to describe the behavior of a digital system by using only descriptive phrases that are defined within a context of a "language" HDLs (hardware description languages) can be used.

## The Personal Computer (PC)

- An excellent example of digital system.

## Binary Number System

- A Binary variable can store either 0 or 1.
- ex) Bin variable  $A \Rightarrow A = \emptyset$  or  $A = 1$
- Unary operation NOT (also called inversion).

$$\text{NOT}(A) = \overline{A} = A'$$

↘ called complement of A

such that

$$\text{NOT}(\emptyset) = 1$$

$$\text{NOT}(1) = \emptyset$$

## How to describe more complex situations?

- We can use groups of bits!
- Ex) Four digit data representation

$\text{data} = a_3 a_2 a_1 a_0$  where  $a_i$  can represent either 0 or 1.

$\Rightarrow \text{data} = 0000, 0001, 0010, 0011$

$0100, 0101, 0110, 0111$

$1000, 1001, 1010, 1011$

$1100, 1101, 1110, 1111$

- A group of bits  $\rightarrow$  word.

$= 2^4 = 16$  possible permutations  
= 16 possible bit patterns

$\text{data} = 0101$  means

$a_3 = 0, a_2 = 1$

$a_1 = 0, a_0 = 1$

## Bit & Byte

- Suffix b – bit and suffix B – byte such that  $1B = 8b$  (e.g.,  $1KB = 8Kb = 8 \times 1024$  bits).

word size	# of values	abbreviation for value
8b	$2^8 = 256$	
10b	$2^{10} = 1024$	1Kb (kilobit)
16b	65,536	64Kb
20b	$2^{20}$	1Mb (megabit)
28b	$2^{28}$	256Mb
30b	$2^{30}$	1Gb (gigabit)
40b	$2^{40}$	1Tb (terabit)

## Data Representations

- Binary numbers can be used to represent anything that we want by designing them in an appropriate manner.
- Ex) 4 directions (left, right, forward, backward)

4 directions  $\rightarrow$  So, 2 bit binary word is required, since  $2^2 = 4$ .

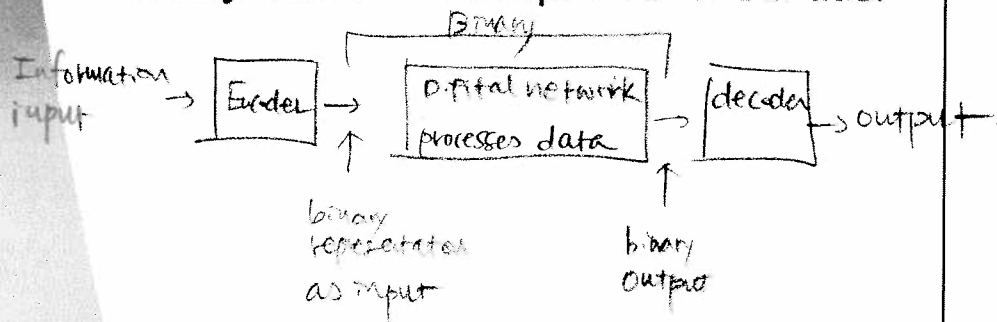

Let's define direction word  $D = D_1 D_0$

$b = 00 \Rightarrow$  left  
 $b = 01 \Rightarrow$  right  
 $b = 10 \Rightarrow$  forward  
 $b = 11 \Rightarrow$  backward

Note that these assignments are completely arbitrary.

## Encoding & Decoding

- Encoding: The process of giving meaning to a group of bits.
- Decoding: The reverse process where a binary number is interpreted for our use.

## Binary and Decimal Numbers

- We live in a world where there are ten <sup>symbols</sup> ~~digits~~ (0-9) -> Decimal number system.
- Digital systems use binary number system in general.
- Dec -> Bin and Bin -> Dec translations are discussed in this section.

## Number Theory

- Each number system has base (or radix).
- Decimal number system's base is 10.
- Each digit can be either one of 10 symbols from 0 to 9 in decimal.
- Base or radix  $r$  for a number system.
- $r=2 \rightarrow$  Binary (Base-2)
- $r=8 \rightarrow$  Octal (Base-8)
- $r=10 \rightarrow$  Decimal (Base-10)
- $r=16 \rightarrow$  Hexadecimal (Base-16)

## Binary to decimal conversion

- To represent 0-9 (decimal) using binary words, 4 Binary digit word is required, since  $2^3 = 8 < 10 < 2^4 = 16$ .

- Let us construct a 4-bit Binary word.  $N = N_3 N_2 N_1 N_0$   
decimal representation is...

$$= N_3 \times 2^3 + N_2 \times 2^2 + N_1 \times 2^1 + N_0 \times 2^0$$

$$= N_3 \times 8 + N_2 \times 4 + N_1 \times 2 + N_0 \times 1 \neq$$

- This shows that a binary digit in  $N_j$  has a base-10 weighting of  $2^j$ .

ex)  $N = 110_2$

$= 1 \times 2^2 + 1 \times 2^1 + 0 \times 2^0$

$= 6_{10}$

means

binary # (base 2)

means decimal # (base 10)

For  $j$ -digit binary #  $N = N_{j-1} N_{j-2} \dots N_0$

decimal # =  $\sum_{i=0}^{j-1} N_i \times 2^i$

## Examples

ex)  $X = 01011100_2$  (8-bit bin #)

$= 0 \times 2^7 + 1 \times 2^6 + 0 \times 2^5 + 1 \times 2^4$

$+ 1 \times 2^3 + 1 \times 2^2 + 0 \times 2^1 + 0 \times 2^0$

$= 64 + 16 + 8 + 4 = 92_{10}$

Bin  $\rightarrow$  Dec conversion can be used to decode binary # output to human-friendly decimal # output.

## Decimal to binary conversion: successive division algorithm

■ Ex) Convert  $19_{10}$  into binary number.

Successively divide 19 by 2 & keep track of remainders.

$2 \overline{) 19} \dots 1 \rightarrow \text{Remainder } R_0 = 1 \rightarrow \text{Least Significant Bit (LSB)}$

$2 \overline{) 9} \dots 1 \rightarrow \text{" } R_1 = 1$

$2 \overline{) 4} \dots 0 \rightarrow \text{" } R_2 = 0$

$2 \overline{) 2} \dots 0 \rightarrow \text{" } R_3 = 0$

$2 \overline{) 1} \dots 1 \rightarrow \text{" } R_4 = 1 \rightarrow \text{Most Significant Bit (MSB)}$

$\Rightarrow 19_{10} = \boxed{R_4} R_3 R_2 R_1 R_0 = \boxed{1} 0011_2$

MSB

LSB

★ The first remainder is LSB.  
The last remainder is MSB

## Continued,

- Ex) Convert  $56_{10}$  to binary number.

$$2 \overline{) 56} \dots 0 \rightarrow \text{LSB}$$

$$2 \overline{) 28} \dots 0$$

$$2 \overline{) 14} \dots 0$$

$$2 \overline{) 7} \dots 1$$

$$2 \overline{) 3} \dots 1$$

$$2 \overline{) 1} \dots 1 \rightarrow \text{MSB}$$

0

$$= 111000_2$$

verification (reverse calculation)

$$\begin{aligned} 111000_2 &= 1 \times 2^5 + 1 \times 2^4 + 1 \times 2^3 \\ &= 32 + 16 + 8 = 56_{10} \end{aligned}$$

same!

## Fractions

- Bin->Dec: a binary fraction can be written in the form...

$$b = 0.b_{-1}b_{-2}b_{-3}\dots$$

- Its corresponding decimal fraction is...

$$F = b_{-1} \times 2^{-1} + b_{-2} \times 2^{-2} + b_{-3} \times 2^{-3} \dots$$

- Ex)  $b = 0.1011_2$  to its base-10 equivalent.

$$F = 1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3} + 1 \times 2^{-4}$$

$$= 1 \times 0.5 + 0 \times 0.25 + 1 \times 0.125 + 1 \times 0.0625$$

$$= 0.5 + 0.125 + 0.0625$$

$$= 0.6875_{10}$$

## Continued,

- Dec→Bin: successive multiplication algorithm.

- Ex)  $0.6875_{10} \rightarrow \text{Bin}$

$$\begin{array}{lcl}
 0.6875 \times 2 = 1.375 & b_{-1} = 1 & \\
 \downarrow & & \\
 0.375 \times 2 = 0.75 & b_{-2} = 0 & \\
 \downarrow & & \\
 0.75 \times 2 = 1.50 & b_{-3} = 1 & \\
 \downarrow & & \\
 0.50 \times 2 = 1.00 & b_{-4} = 1 & \\
 \text{since it is 0, stop!} & & 
 \end{array}$$

$$\text{So, } 0.6875_{10} = 0.b_{-1}b_{-2}b_{-3}b_{-4} = 0.1011_2 \quad \#$$

## Round-off error

- The accuracy of the translation from decimal to binary depends on the number of bits that are used in the base-2 word.

- Ex) 4-bit binary fraction  $X$ .

$$\begin{aligned}
 X &= 0.X_{-1}X_{-2}X_{-3}X_{-4} \\
 \text{decimal} \Rightarrow X &= X_{-1} \times 0.5 + X_{-2} \times 0.25 + X_{-3} \times 0.125 \\
 &\quad + X_{-4} \times 0.0625
 \end{aligned}$$

Let's consider two very similar binary fractions

$$X_a = 0.1110_2 \quad \& \quad X_b = 0.1111_2$$

## Continued,

Substituting gives...

$$x_a = 0.8750_{10}$$

$$x_b = 0.9375_{10}$$

- The smallest resolution allowed is 0.0625. So, it is not possible to represent numbers between these decimal values using the 4-bit binary fraction.

## Round-off error calculation

- Ex)  $0.9270_{10}$  can't be represented exactly using the form  $0.x_1x_2x_3x_4$

The closest one is  $x_b = 0.1111_2 = 0.9375_{10}$

$$\Rightarrow \text{round-off error} = \frac{|0.9375 - 0.9270|}{0.9270} \times 100 = 1.13\%$$

## How to overcome this problem?

- Add more bits to the binary representation.

■ Ex) 5 bit binary fraction  $0.11101_2 = 0.90625_{10}$   
 6 " "  $0.111011_2 = 0.921875_{10}$

Getting close to the actual value,  
 but there still exists round-off error.

## Hexadecimal (base-16, radix $r=16$ ) numbers

- It has 16 symbols for each digit.

0 ... 9 A B C D E F → either upper or lower case  
 ↓ ↓ ↓ ↓ ↓ ↓  
 10 11 12 13 14 15<sub>10</sub>

- Each digit is called "Hex" digit.
- Hex → Bin and Bin → Hex conversions are easy due to the fact that 4-bit binary word is equivalent to single hex digit.

## Examples

$$H = 304E_{16}$$

$$\xrightarrow{\text{decimal}} 3 \times 16^3 + 0 \times 16^2 + 4 \times 16^1 + E \times 16^0$$

Each Hex digit can represent 4-bit binary number.

$$0_{16} = 0000_2 \quad \dots \quad F_{16} = 1111_2$$

ex) 1001 1100 1110 0101<sub>2</sub> to Hex  
break it into individual 4-bit groups.

$$\begin{array}{ccccccc} \boxed{1001} & \boxed{1100} & \boxed{1110} & \boxed{0101} & = & 9CES_{16} \\ 9 & C & E & 5 & = & \cancel{9CES} \end{array}$$

or 9CESh

↓  
Assembly  
convention

C-language convention

## Cells & Hierarchy

- Cells: fundamental building blocks to create a digital system.
- Logic diagrams: Graphical representations of digital networks can be used for both analysis and design.

### Ex) 3 binary input variables and one output cell

The input & output points of the cell are called ports. They allow the cell to be connected to other cells.

Ex) An example of a function

$$\begin{cases} f = 1 & \text{if } A \text{ or } B \text{ or } C = 1 \\ f = 0 & \text{otherwise.} \end{cases}$$

### Creating a large system

- Use small cells to build larger cells with more complex functions.
- Signal flow paths ( $\equiv$  transmission wires  $\equiv$  interconnects) are used to interconnect cells.
- Ex) Serial data flow path connecting two units.

## Continued,

- Ex) Parallel data flow connection.

Four separate wires are used to transmit all bits simultaneously

What if two wires cross one another? → use a black dot

no connection

connection

## Hierarchical design

- The idea of using cells as building blocks is called "hierarchical design".
- This concept gives us a structured technique for analyzing and designing complex digital systems.
- Two approaches to designing a digital network:
  - Top-down: start with large-scale system specs then choose the cells that are needed.
  - Bottom-up: start with basic cells to build more complex cells.

## System Primitives

- A system primitive: a basic function that is used several times to create the entire unit.
- Clocks: a periodic signal to synchronize operations. Always makes a transition from 0 to 1 and back.

period (T) : the time for one complete cycle.

Frequency (f) :  $f = 1/T = \text{\# of cycles/sec}$   
usually given in units of Hertz (Hz)

## Examples

(x) 1 Hz = 1 cycle/sec

1 GHz pentium processor's clock generates 1 G cycles/sec. Thus, the clock frequency can be used for measuring system speed.

(x) freq  $f = 50\text{MHz}$  calculate T.

$$f = 1/T \Rightarrow T = 1/f$$

$$T = 1/f = \frac{1}{50 \times 10^6} = 2 \times 10^{-8} \text{ sec}$$

$$= 20 \times \underbrace{10^{-9}}_{\text{nano}} \text{ sec} = 20 \text{ ns (nanosecond)}$$

## Measurement units

Decimal	Unit	Bin #s (for mem sizes)
$10^3$	K (kilo)	$2^{10}$
$10^6$	M (mega)	$2^{20}$
$10^9$	G (giga)	$2^{30}$
$10^{-3}$	m (mili)	NA
$10^{-6}$	$\mu$ (micro)	NA
$10^{-9}$	n (nano)	NA

# Logic gates

- Takes input bits and produces an output bit as defined by the logic operation.
- Ex) AND gate & OR gate

A	B	F
0	0	0
1	0	0
1	1	1

## Truth table

AB	f
00	1
01	1
10	1
11	1

## Continued,

- Ex) Memory cell: capable of capturing and holding the value of a binary variable.

- Suppose input  $D = 1$ . Then, "1" is stored (= written or loaded) in the memory cell. Once a data bit is stored in the cell, it can be accessed (or read) at the output port  $X$ . The clock  $\Phi$  is used to allow the operation to be synchronized with the rest of the system.

## Continued,

- Registers: A register is a block of memory cells that can be used to store words. a word

- This allows for parallel loading and reading of an 8-bit word, synchronized by a clock signal  $\Phi$ .

## Design Metrics

- To compare different design solutions, we introduce the concepts of a metric (a unit of measurement).
  1. Temporal metric (time): ex) 1GHz vs 2GHz CPU.
  2. Size: PCB based system vs. SoC.
  3. Electric power consumption: ex) cell phones (battery life 1hr vs. 2hr).
