

# CpE 213

## Digital Systems Design

Lecture 19  
Thursday 10/30/2003

UNIVERSITY OF MISSOURI-ROLLA  
The Name. The Degree. The Difference.

## Announcements

- Exam 2: Thursday Nov. 13<sup>th</sup>
- Review session: Tuesday Nov. 11<sup>th</sup>, from 7 to 9 pm in G31 (this room).
- See me or send me email if you have another exam on that day.
- Check your grades on blackboard and notify me of any discrepancies.
- Group exercises are for attendance check, please only write names of group members actually present.

# Stepper Motors

- A Stepping Motor System consists of three basic elements, often combined with some type of user interface (Host Computer, PLC or Dumb Terminal).

- The Indexer (or Controller) is a microprocessor capable of generating step pulses and direction signals for the driver.

Adapted from <http://www.ams2000.com/stepping101.htm>

# Stepper Motors

- The Driver (or Amplifier) converts the indexer command signals into the power necessary to energize the motor windings. For 8051, can custom-design driver from power transistors or use off the shelf packages such as ULN2003.
- The stepper motor is an electromagnetic device that converts digital pulses into mechanical shaft rotation.
- Used for position control in disk drives, dot matrix printers, robotics, etc.

Adapted from <http://www.ams2000.com/stepping101.htm>

## Pros and Cons

- Advantages of step motors:
  - low cost, high reliability
  - high torque at low speeds
  - simple, rugged construction that operates in almost any environment.
- Main disadvantages in using a step motor:
  - resonance effect often exhibited at low speeds
  - decreasing torque with increasing speed.

Adapted from <http://www.ams2000.com/stepping101.htm>

## Stepper Motor

- Has a permanent magnet **rotor** surrounded by one or more **stators** with center-tapped common.
- Usually four stators (four-phase).
- Center tap allows change of current direction in each of two coils, resulting in polarity change.
- Polarity change causes movement in fixed repeatable increments (steps).

# Stepper Motors

- Uses square wave for excitation
- Alternatives:
  - DC motor+PWM+feedback
  - AC motor+AC excitation+feedback
- Unipolar or Bipolar varieties
  - Unipolar: current flows in one direction through centertapped windings
  - Bipolar: current flows in both directions through windings

## Unipolar Stepper Motor

## Stepper Motor Basics

- Each step may only be a few degrees
- Step rate limited by motor inertia
- Example
  - One step equals 6 degrees
  - One step per millisecond

$$\frac{6^{\circ}}{10^{-3} \text{ sec}} \times \frac{\text{rev}}{360^{\circ}} \times \frac{60 \text{ sec}}{\text{min}} = 100 \text{ rpm}$$

## Stepper motor driver

```
/* Try sketching a schematic diagram for this.
   Questions:
   1. How fast does the motor go? (in RPM)
   2. What changes should be made to go in reverse?
*/
#include <reg51.h>
unsigned char code pattern[] = {0x5,0x9,0xa,0x6};
void msec(int);
void step(void){
    static unsigned char i;
    P1= pattern[i=++i&3];
    msec(8);
}
void main(void){
    while(1){step();}
}
```

## Assembly code driver

STEP:

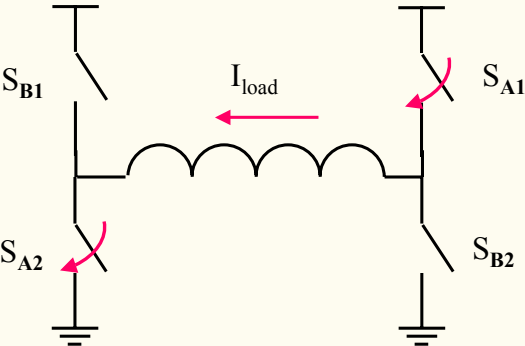

```
0000 0500      R      INC      i
0002 E500      R      MOV      A,i
0004 5403              ANL      A,#03H
0006 F500      R      MOV      i,A
0008 900000    R      MOV      DPTR,#pattern
000B 93              MOVC     A,@A+DPTR
000C F590              MOV      P1,A
... + call to msec and return.
```

## H-Bridge Example

- Required for **bipolar** stepper motors
  - current goes through windings in both directions
- Allegro UDN2998W Dual Full Bridge:
  - $\pm 2\text{A}$  Output Current, 50 v supply voltage
  - -0.3v to 15 v logic input voltage range
  - Internal protection diodes for inductive load
- See: <http://www.allegromicro.com/control/motors1.htm> for more details

# Allegro 3996 H-bridge

# Simplified H-bridge

The diagram illustrates a Simplified H-bridge circuit. It features four MOSFETs:  $S_{B1}$  (top-left),  $S_{A1}$  (top-right),  $S_{A2}$  (bottom-left), and  $S_{B2}$  (bottom-right). The gates of  $S_{A1}$  and  $S_{A2}$  are connected together, and the gates of  $S_{B1}$  and  $S_{B2}$  are connected together. The source of  $S_{A2}$  is connected to ground. The source of  $S_{B2}$  is also connected to ground. The drain of  $S_{A1}$  is connected to the drain of  $S_{B1}$ , which is connected to a load inductor (represented by a series of loops). The current through the load inductor is labeled  $I_{load}$  with a red arrow pointing from right to left. The load inductor is connected to the drain of  $S_{A2}$ , which is connected to ground.

## Bipolar Stepper Pattern

- Only two bits needed instead of four
- Pattern is: 11, 10, 00, 01, ... (grey code)

Phase1

Phase2
